You can make it as complicated as you want too...for example: global warming actually could contribute to the next ice age happening. As the earth's oceans warm, the natural circulation of the oceans such as the Gulf Stream and the one that comes down the west coast (can't remember its name) could change. Melting ice will have a great affect on this circulation by actually lowering the temp of certain bodies of water that are historically warmer. I find it all interesting.

I don't so much believe that global warming is a result of man by itself as much as I have trouble believing that over the number of years that we have existed on this planet, that we didn't manage to have very serious negative impacts...
