So if I understand this correctly the "swing" occurs when the fly moves from the bank (or close to it) to wherever you are standing in the stream. The line ends up in front of you hanging in the current?

Correct.

The "swing" is merely the current pulling the fly down the current and eventually directly below you. Swinging wets is particularly effective in the period from about early April till mid June when insects, esp caddisflies, are most active. These bugs swim to the surface when hatching and trout are often attuned to look for movement during these times. The flies you described are time tested and definitely work.
