I do make sense out of it, and agree to a given point. I just think it is a poor predictor of spinner fall for a given evening.

Several days worth of poor hatches falling all at once will still outnumber 1 day's worth of a strong hatch.

If a hatch has 10 days of spinner falls, only 1 or 2 need to be especially successful to ensure the next generation. I think you overestimate their success rate. Well more than half of the bugs may fail at their 1 mission, and that number can vary greatly year to year.

Like many other species, the mayfly's evolutionary strategy is overkill. i.e. a huge number of bugs in a short time period, each capable of producing a huge number of offspring, but a relatively pitiful individual success rate.
