Myself, gone4day, I believe pcray was involved in related threads, and some others. Somewhere in the archives there is at least one thread that shows the math involved.

As I indicated above it's the cumulative effect that needs to be managed. And yes, when flows drop to summertime levels the total withdraw **should** be further limited. There **should** be a minimum level at which point all withdraws would stop until flows increase. There are a number of ways formulas to determine acceptable withdraw rates could be managed. I believe there were some suggestions in previous threads on the topic. [/quote]

See, at least you use the word "should". I wonder if the drilling companies will.
