I forget what show it was, but it was some bass fishing show where they have a biologist come on and give fishing tips. I forget the exact numbers but he said they found in studies that a bass' forage base, no matter the size of bass, was 80-90% food items 2-3 inches in length and under. That's bass but i imagine the same principle is at least somewhat applicable to trout. He did say that yes larger fish can and will eat larger prey than a smaller fish, however he felt that most fish stick with the small stuff because of the risk reward ratio.
