Ok gentleman, 1-1/2 to 2x the water depth sounds right (at least that's what I got off the net from Kelly Galloup), but given current variability, when, how do you make adjustments?

If I am not seeing my indicator twitch at all from occasional bottom contact, I will increase the distance between indicator and fly until I do, a few inches at a time. If it seems like the fly is not getting down to the bottom quickly and I cannot correct this by casting farther upstream and mending line, I will start adding weight. If I start snagging the bottom I will decrease the distance between the indicator weight/fly until it is no longer a problem and also possibly decrease weight. I try to strike a balance between weight and indicator position. Too much of either is not good IMO.
