the nymphs after hatching from the eggs go through instars where they shed the exoskeleton as they grow. most may flies go through 5 to 7 of them in the course of their lives. Thats when you can find them in a white state. just like a blue crab does in a way...mmmm soft shell crab sandwich (sorry no lunch) stone fly's go through it, most of the Perla were small so still have to shed and grow. A lot of the other nymphs were so small didn't even collect any (size 24-28) when fully grown will be (14-20).
