i was on afishing trip with some friends and we stopped by our "honey hole" of a farm pond, with like 5 pound bass in it :). when we arrived, dozens of sunnies floated on the surface, and a bass lay dead in the algae. they were all in the water and some of them looked very old, while one, in the pictures, we watched die. they would settle to the bottom, and then start swimming around again but upside down and everything like that. on estimate, over 60% of the fish above 4"are dead or abou to die, adn about 30% more have the same charicturistics of sores that seemed infected. they also appeared to have pop eye. could a virus be affecting their slime coats? ill try and post the pictures once they get downloaded. (my computer is really slow.
