The photo posted was definitely a crane fly larva.

The photo that someone posted of a caddis pupae, that's what caddis pupae look like.

If you want to see one, open up a grannom case (if they haven't all hatched out yet on your stream). The ones that haven't hatched yet, are now in the pupae stage.

If you open up one of the cases earlier in the season, they would still be in the larva stage.

Probably TroutNut.com or some other site has a photo of a Grannom case. They are very distinctive. And streams that have good Grannom hatches have loads of these cases on the rocks.

It's kind of hard to open the case without turning the bug inside to mush. The best way I found is to carefully cut the case open with your flytying scissors.

pics of above from Troutnut - <http://www.troutnut.com/specimen/673>
