Guys you are talking about high summer temperatures, ie, sir temps vs water temps, they are 2 very different things. PFBC shocks streams during the summer, the sections PFBC shocked is cold water, not highly impacted by high water temperatures. There is little risk to the fish as long as the temps are below 70. The sir temps can be as high as 100° while the water temp is in the 60'S.
I'm not saying those are the temps just using an illustration.
