I agree with Mr Idiot. Overspill from Spruce Creek pellet pig progeny or perhaps pellet pig progeny procreated in appropriate pebble areas of the Little J.

Interestingly this year for the first time I caught a wild bow in the Muddy Creek Watershed. Then 4 months later I hear from a club near the area I caught it that they are catching many wild looking bows. They send pics I confirm and say I would be doubtful if I hadn't experienced it myself near there in May.

During the first year there are many smaller nursery waters for the fry to fingerling to survive, when they become 4-7" long they need to occupy the lies of larger fish which push them out, downstream to bigger water, warmer times in summer push them back up where they have to compete for cover and food. It is at this time where the rubber hits the road for their survival. Can they outcompete the resident wild browns who have a foothold within the watershed? Then continue through the next year as larger fish with the same cycle only now make it through to sexual maturity in the larger warmer creek. This will be the test to see if the population continues to be robust.
