If there's a low density wild Brown pop (which I was not aware of until this thread), my guess is you will also have a low density wild Bow pop in few years, assuming a viable quantity of "fingerlings" are being introduced. Any idea on the number of fish stocked Mike, can you release that?

For whatever reason on the whole Bows are not as efficient at spawning in PA streams as Brooks and Browns, but I still think it happens on a limited basis in more places where Bows are stocked than one would initially think. Outside of the streams where they're abundant, I've found Rainbows to be streaky spawners in streams with marginal conditions...they'll have a good year and then they'll be fairly abundant for a couple years after that. Then they seem to disappear for a few years, only to reappear a few years later after another relatively good spawn.

Squatch - I think Bows in another Lanc Co. stream you know had a fairly good year in the last couple of years...
