That #8 well flow back was definitely a problem and Atlas was cited for that issue. The fire did melt the top edge of the pit liner but only a very small amount of the pit contents spilled out one corner. The fire went out when it reached the water level in the pit. Nothing got into a stream or groundwater. All soils pulled up and disposed of. No long term or near term affects for that matter. The fire was the result of a companies inability or miscalculation on how to separate the large amounts of condensate that the well produced. Also, a light plant was to close to the pit which ignited the condensate vapors coming off of the pit. Some companies were caught unprepared for the large amounts of condensate found in this particular area of the Marcellus shale. New methods and protocols were put in place to keep from happening again.

SO what I get from that is.....The gas companies rushed to do something and were not prepared for what they encountered. Its ok though, because you say it won't happen again.
