"Drag free drift" refers to a natural drift of the fly with the current, just like a real insect would float/drift along. Drag is the fly drifting in an unnatural (usually faster, but can be slower or not moving parallel to the current too) manner. It is caused by the varying currents in the stream bed pulling on your fly line and leader, and then in turn your fly. Fish can tell when a fly isn't drifting naturally and will often refuse to take it if this is the case. Good advice above about not focusing as much on fly selection and focusing more on proper technique to start...The wrong fly with the right presentation will catch more fish than the right fly with the wrong presentation.
