As much as geology has a lot to do with it, something else has happened recently - in the last 20 years. It could be that the soils, as poor as they are in that area, have completely lost an buffering ability and now the streams "spike" with precipitation events. Maybe it's something else.

But I know that the fishing has gone downhill. I know that there is a large catch and keep factor there, but there always has been. The streams don't hold stocked fish well anymore, and the wilds are all but gone.

Those of you who have been doing the water sampling on Spring Creek, have you actually seen big pH drops with heavy rains and/or melting snow, and how low does the pH drop in these events?
