Fish eat what's alive, they don't want carrion. Your flies are wonderfully inert little specimens of non-life. They don't have nearly the amount of draw as OldLefty's example which lack the photorealistic touches to them but make up for it in fibers that will move and pulse in the water, hold tiny bubbles of air, and generally look like something alive.

Tying lifelike bugs isn't something new, its simply something that didn't work so people went bzck to wrapping a feather on a hook.

Your dealing with a fish that has a brain the size of a pea. Don't overthink it.
