what exactly is the walts worm imitating? or does it just look tasty? im intrigued

It's suppose to be a crane fly larvae, but it also looks fairly generic, IMO. But it's tied in the round, which I think is the most important aspect of it.

I've always had a lot success with nymphs tied in the round, or that are very subtly asymmetrical. When nymphs tumble in the current I think they stay more upright then we give them credit for. I feel like it's harder to distinguish a fly that is tumbling incorrectly when it's tied in the round, as oppose to when it has a fancy wing case, legs, weaveing, etc.
