Probably mentioned in the past regarding the WW: Especially underwater fish including trout take all kinds of things into their mouths that come to them via the drift just in case it's got nutritional value. If it doesn't, they spit it back out. The walt's worm in various sizes and degrees of bulkiness looks like quite a few things we know and probably quite a few we don't. It also has little in the way of spook factor since there is no flash and nothing about it hampers natural drift.
