here's the apple caddis

its a easy tie really.little info from jerry hadden;

Fishing a pupa imitation during a B. appalachia emergence seems to be somewhat of a mystery. More than one experienced angler has questioned the fact that with so many naturals hatching why isn't fishing a pupa imitation more productive? While other caddis are emerging drifting a pupa just under the surface or in the surface film produce fish consistantly, but during this hatch produce very few. Almost ever fly fisher I've talked to has expressed the fact that fishing a pupa during a B. appalachia in the surface film produces very few fish. However fishing them deep especilly mornings prior to the hatch produces consistantly. The answer comes with looking at the insects habits. Before hatching B. appalachia will become active by attaching silk thread to the substrait, from which they hang suspended near the the river bottom. This seems to accure in the morning qiute sometime prior to the actual hatch activity.
