I checked 3 stream gauges that I monitor regularly, and all 3 streams are at near perfect fishing levels.

You can't determine good flow levels for a stream by looking at the color of the dot. Because the color of the dot is based on current flow compared to average flow, for this particular date. But the average flow varies greatly for different dates. So a particular rate of flow will show up as an orange or red dot now. And the exact same rate of flow will show up as a green or blue dot at another time of year.

You have to look at the actual flow in cfs, and know from experience what flow levels are high, low, and a good fishing level on that stream.
