I have an android phone application, RiverFlows, that shows usgs flow data for five streams that you choose. Once you select a certain stream, data is given in a full-screen chart for the last seven days. This chart doesn't give the colored dots based the current flow compared to the historical flow levels for this date, which I think is good, because the historical averages vary a lot across the months.

My guess is that NE stream levels are OK, and actually not too high for dry fly fishing, when blowouts could be a problem this time of year. Water temps are probably lower than I would like, but at least the streams aren't too high... yet.
