As a geologist I never give faults and movement deep beneath the earth's surface much thought in my daily life. (all faults have moved and will move again even if in geologic time, just think very long time) I don't think about it because it is constantly occurring somewhere around the world. And we will have earthquakes because of it. Those quakes that you feel are small and maybe the disposal of fluids caused some small quakes and kept a very large one from occurring by not allowing that pressure to build very high. That being said, disposal wells need to be sited using good science and technology and I should say that most are done this way. I can't speak for the one in Youngstown but rumor has it that they were deeper than what they reported to the state and were required to plug it back to the formation that they told the state that they were going to dispose into.

2 years ago I was in Virginia Beach on vacation when the earthquake hit in the Charlottesville VA, area. I was on the 8th floor of a beachfront hotel and my 5 family members felt and saw the hotel sway back and forth for about 3 seconds or so. Very odd feeling. Absolutely no fracking or waste disposal anywhere near this site. Good old Mother Nature!
