Ohhh, so it's your "fault." 😊

I'm not a geologist, but you probably can figure that out. I just find it to be a very interesting subject. I did take a couple course on it, but only know enough to figure out that you weren't talking our of your ass on the first one.

I agree with you that this was no big deal, nor could it have been at that location. The sky is not falling, nor could it have fallen at that location. The geology is not conducive to large earthquakes, and that fault was very old and very inactive.

Your statement about that well being deeper than it was supposed to be also makes sense to me. How else could on explain why the epicenters were 2500 feet below the well unless the well was deeper than reported.

As far as I know, they were never allowed to resume disposal at that wall.

It was a learning experience for the industry and rules were changed as a result.
