take a couple flies that are straight from the vise and toss them into a cup of water. If they float normally then maybe you should adjust your casting/leader setup. If they land on their side still then it's your tying. I'd start there and move on.

I don't tie my posts very tall, just maybe a quarter inch above the top wrap. If there's too much material on top then it will tip over. You want the body and hook to weigh more than the top half. You also could be over hackling the parachute too, which whill cause more weight on top.

Just a few thoughts.
