PA freestones in that size class running through a typical valley for the region (somewhat narrow) often don't care about your hard work and devices. They jump around within the confines of the valley and follow the path of least resistance. Sometimes, that will be where you want them to go, right through your devices. Just as often (if not more often..), within a couple years of the work being done, they'll decide to go elsewhere and leave your work high and dry. Its kind of the nature of the beast.

Just a viewpoint...

Excellent observation RLeep. Geologists call it an incised valley. Streams naturally meander back and forth across the valley floor. If you actually look at the internal structure of floodplains, they inevitably have buried stream channels in them. The Miss. river for example has an incised valley that's 150 mile wide in places.
