Exactly

Done by one of the top designers to eliminate dead spots and create a more efficient rod

The irony of this is that amongst rod builders, sanding through the carbon material of a blank is generally considered a bad idea.

You would think that it would create more problems than it could possibly solve. I find the whole thing to be confusing. They should have near perfect control over how the blank turns out, so why would they need to go back and tune it. It is a predictable and homogeneous synthetic material.

I think my confusion is just further evidence that I would never make it in the world of marketing.
