It doesn't surprise me. The invaria hatch was very clearly on in MID-April last year, dorothea's had started by the end of April! With last year's hatch being so early, that means eggs were laid early, nymphs hatched early, started growing early, etc.

Assuming typical weather like we had this year, the hatch should slowly work it's way back to a more normal time. But it might take a few years.

Les, yes invaria's come first (size 14ish, yellowish-orange duns, darker spinners), and dorothea's second (16-18, whitish yellow duns, spinners yellowish orange). I've never heard an invaria called anything except a sulpher. They are THE sulpher. Dorothea's are also typically called sulphers, but PED is common in some places.
