With last year's hatch being so early, that means eggs were laid early, nymphs hatched early, started growing early, etc.

That's my theory too. Last year's hatches were so early that this year's bugs got an early start on life, so are maturing early this year, even though it's been a cool spring.

QG's, Hendricksons, grannoms all hatched early last year.....right on time this season. Unusually cold spring temps delayed hatching.

When you see hendricksons...fish hendricksons.....when you see sulphurs...fish sulphurs, etc. 🙄
