Blue Marsh is a little different than most places due to the dam.

Essentially, they'll pull water from the top until it gets too warm for trout. Once it surpasses a certain temp, then they start adding colder, bottom water, to bring it back to around 70 F or so, increasing the amount of bottom water as needed to keep it from going up any higher, but not making it any cooler (which would be a waste of the limited cold water).

It will pretty much then hold at that temperature until they run out of cold water at depth in the lake. From there, they can't really control it and it gets too warm, rather suddenly. I'm sure someone could give you the exact temperatures and rules and so forth.

Might as well fish it if you want. They're stockies. Very few will survive the summer anyway. They'll put more in next fall to replace them.
