When the cool water pool is exhausted, the Tully really gets warm. and Cacoosing and Plum (the tribs in the DH sections) offer little in the way of a cool water respite for the fish.

Nowadays the stream seems to get *really* warm hot (see below). I can't access the data from back in "the day," but i seemed like there was more cool water and the fingerlings seem to make it through the summer in better shape and in greater numbers. Perhaps the cold water pool was larger back then?...don't really know.

I have witnessed fish being lethargic and gasping for air well before the hottest time of year. I really gave up fishing there as soon as the weather turns warm for that reason.
