Not so. The Tully where the lake now sits was a smallmouth bass, redbreast sunfish, rock bass , white sucker, American eel, and carp creek.

Furthermore, reducing the Lake water level through the summer would have no positive impact on downstream temps. As the lake's fisheries manager I would never recommend it from a lake fishery standpoint unless it was done to develop a vegetated shoreline that could be flooded the following spring to enhance reproductive success and juv habitat for certain lake species.

Mike is absolutely correct. The Tully (at the point of the dam and down-stream) was a warm water species stream until Blue Marsh dam was built.
