I refer to that stream as a sewer or carp farm but somehow, someway....the trout manage to survive. I think that they can withstand temps in the high 70's for longer than we would be led to believe. It's almost like they are in hibernation / catatonic state. If we don't catch them, o think the carryover numbers would be surprising. You find them living in the Swattie, Susky and other waters that near or exceed the 80 mark. The thing that burns me about the Tully ate the guys fishing every morning during tricos when the temp starts out at 71 degrees. They catch and release during the heatwaves / dog days. That's probably killing more than herons

and of course they do this at cacoosing because it is by far the largest thermal refuge on the stream.

fwiw, during the heatwaves Plum is typically warmer than the tully even after the cold water pool is exhausted.
