I am not sure about the discharge temperatures. I believe I am taking a trip to the plant next week. I will find out then.

As far as volume is concerned, that varies greatly between 400 to 6000 gallons per minute treated and discharged. I believe the average is around 2000 gpm.

I am not sure of the average water temps in the Bennetts. It may get too warm to support wild trout, with or without the plant discharge adding a shot of cool water to it. Especially since our lowest flows will typically coincide with when it would need the cool water the most. Unfortunately, the Hollywood plant was under construction when I was hired, so I wasn't involved in any of the sampling or planning phases of the project.
