It contradicts ongoing research by USGS that says they can determine the origins of the brook trout and whether or not they are natives, natives that are a heritage strain, natives mixed with stocked fish, stocked fish. The USGS study even can determine the stream of origin. USGS determined there was mixed genes in many populations of brook trout, but that there are many streams with heritage strains.

I disagree that it contradicts any of that.

Clearly in the study above it shows that they can tell the difference, same as USGS. They just were not seeing interbreeding which does not contradict the USGS at all. It just does not support it. There is a difference in this case. IMO of course.
