I know they die but do they suffocate and just float to the surface

Sometimes.

It's not uncommon to see a released trout in warm water immediately go belly up or otherwise fail to revive upon release. More likely, in warm water a trout will swim away and appear to be fine but due to low oxygen and high lactic acid in their bloodstream, it may take longer (perhaps days) for the fish to die. Even more likely, I think, would be death over a period of months due to an accumulation of stress from multiple sources.
