They had excess water coming in the reservoir for the past 2 weeks, at one point the outflow was at 3000cfs, they kept releasing high flow levels until things were almost back to normal (meaning inflow equals outflow with storage at 1370) and then they released 750cfs for the white water release this weekend, dropping it way down to 250cfs at 1pm. This is the beginning of the warmest part of the day while we are currently have the warmest weather so far this year.

This created dramatic water temperature spikes, not very good water management if you ask me. They had excess water fully knowing there was going to be a white water release and no major precipitation in the forecast. Now the reservoir level is below normal pool and they are holding back water.

Absolutely no regard for the trout, shameless.
