I fished Sat and Sun this week on two different streams with two different methods. I nymphed using 5X Sat and Tricos with 7X on Sunday. I hooked fish both days and had the hook get dislodged during the fight. When that happned on Sat and I checked the fly I did not notice anything strange about the tippet. Yesterday after I lost fish and hook came free and I checked the fly I noticed the line had colied close to the fly. I've also noticed this while tying new leaders and straightening the tippet where I went too far and the tippet sprung out of the straightener. On larger diameter material nothing happened to the material but on smaller diameter it coiled and I had to straighten it very carefully because the smaller stuff seems to hold that "pressured" coil much more than the spool memory coil. I'm juust wondering if that coil acts like a spring and does not allow a very light fly to move properly.
