The next time I'm up that way, if I remember, I'll take some water temperature readings in various locations. Of course I have no base data to compare it to.

I was hopeful from the statements from the PFBC that the discharge would keep it cool enough to support a wild trout fishery for at least some distance.

Just take the water temp of the discharge from the plant. And the water temps in the stream just above the discharge. Preferably on a warm afternoon with low to medium flow.

Did the PFBC make any statements about the temperature of the discharge?

I saw statements about improving water quality, but no mention of water temps.
