Now we talkin.

OK now that I have some direction, and how to focus on it, do you feel that the water temp has a lot, a little or no effect on this particular hatch, or any hatch for that matter generally speaking? My experience is that these kind of streams vary in water temp suddenly, depending on the amount of rain, and cloud cover. Im talking about the recent weather in that area. Seems like it has been raining a whole bunch (almost every day) so the water may be pretty cloudy and a little colder (hopefully). These smaller streams may be useless to fish if they are washed out at least for a while, but there is that perfect medium I am looking for. I guess the means of my question is how does water temp effect a known hatch depending on the size of the stream/river... and based on that, what is the prime water temp for a decent hatch? More or less am I making a mountain out of a mole hill? haha.
