I can tell from experience anything we do structure wise in a stream environment will eventually fail. Even chop and drop can fail if not done so that the trees can be washed away.

The trouble is most streams have been so impacted by human intervention that it's nearly impossible to find water that hasn't been impacted, and it's very hard to reverse. Good example is any stream you pick in a state forest that has a trail along it there's almost always some impact. A lot of times it goes back way before the trail was built, usually to the logging days.
