I just returned from Vermont and something that I find really interesting is how transient the fish populations are... they move around A LOT. While I don't really think the RT fingerlings will survive in Donegal for very long but isn't it a little early to speculate where all the fingerlings went?

Using Vermont streams as an example here... many of the streams there get warm in the summer so the fish move to heavily oxygenated riffles and cold tribs or nursery waters.

I think one of the problems with fisherman in Pennsylvania is that we want OUR TROUT to be in OUR FLYFISHING ONLY STRETCH or OUR ATW. Well it doesn't always work that way... fish move.

There are plenty of trout streams that are devoid of trout in the summer months... doesn't mean the trout are not surviving... if you think that is the case look at the Delaware River system and howw much those fish move around.
