My point is this. pcray stated more than once that doe season is timed to be after the rut so that the majority of does are pregnant when they are killed, for maximum effect.

It doesn't matter when you kill a doe in the fall, before she's bred or after she's bred, it will have the same exact effect of no fawns from those dead deer the following spring. He is stating that the goal of rifle season is to get does pregnant before we shoot them (for maximum effect) and that is not the case at all.

The average number of fawns per doe in PA is slightly less than two and a lot of it has to do with where they live. You cannot say that on average you are killing three deer with one shot for reasons I posted earlier in this thread.
