So are you guys saying that the premise that a super high biomass of fish in a small stream stunts the growth of fish is completely wrong?

I've been discussing this on a board for fishing in the Smokies. Many of them harvest down there. Several believe it is helpful to bringing back "larger" fish. One person said, "In a normal stream where you might have 300 trout per mile, I wouldn't advocate harvesting. In our streams we have anywhere from 3500-4500 fish per mile."
