Hey guys. I just got done tying a few emerald shiners for an upcoming steelhead trip. This is my first time using an epoxy to form a head on a fly. I bought loctite brand epoxy from walmart after talking with bob in volant who told me to just get a general epoxy. So far things aren't going so good. After making a decent epoxy head on one of the shiners I let it sit to dry for a few hours. I however came back to find that the epoxy soaked into the thread and the head I made was pretty much non existent. Have any of you had this problem before? and if so how do I prevent it from happening again. Or is there a better epoxy I should get?
