Thanks Dan...I thought I remembered a thread like that, but couldn't dig it up when searching earlier. I'm not sure where they shocked it, but there are sections with good, classic limestone spring like habitat on that stream. There are also sections of poor habitat, but there's still fish in them too.

I once got scolded by a Sasquatch for walking through the "poor habitat" on that stream and not fishing it. He promptly hooked up with a Brookie in a stretch that I was ready to walk right through. I've fished plenty of high biomass, and plenty of low biomass streams, and this one doesn't fish like a low biomass, poor Trout stream. It feels and fishes like a B or low A.

If those class Browns are wild and present in the stream, at that size, they'd quickly change the biomass numbers.
