they sink, that's why i don't use them on streams - great for nymphing lakes and the salt, but i always found that after a number of trips the first 6" would sink.

DT's i don't have an issue with - never treat the line. they last maybe 2 years then i switch them round.

imho if your having to treat your fly line, you either need a new one or its the wrong type, in which case you need a new one too...

You truly believe this? That the taper of the line affects how well it floats?

That the thicker middle portion of a DT line somehow makes the last few inches float better? That the thinner running line section of a WF line makes the last few inches tend to sink?

You may very well have had better luck with your DT lines, but I can't say that I agree with your idea of DT's being inherently better floating lines. It makes no sense.

+1 to PK

Same front taper except WF narrows to a running line.
