Hi all,

I'm new to the site as a member but i have appreciated all the great content this site offers for some time. Since there seems to be some pretty knowledgable individuals posting on this thread i thought i'd jump in and pose a couple questions i've been pondering for some time.

1.) The common belief perpetuated by the industry is that injected fracturing fluids will never return to the surface (except from the well bore as produced water). My question is, if oil is able to migrate from source rock deep below (thousands of feet) into sandstone reservoirs as it has in many of the prolific oil and gas basins around the country, why can't water migrate in the same way? I can understand that the timeline for this upward migration very long but how long? Won't this water eventually make it's way upward?
