Fisheries Society The History and Dissemination of Whirling Disease "

New Zealand mudsnails most likely are transported by fishing equipment including felt soles. Here's a quote from "Richards et al, North American Journal of Fisheries Management, 2004, Simple Control Method to Limit the Spread of the New Zealand Mudsnail *Potamopyrgus antipodarum*". "It has been our observation that commonly used lace-up wading shoes are good transport mechanisms of *P. antipodarum*, which often get wedged in-between laces and shoe. Felt bottomed soles can also house *P. antipodarum*, therefore, in addition to desiccation or freezing treatments we recommend a thorough visual inspection and removal of snails."

Felt is not a likely culprit in the transfer of Whirling Disease, but it is for mudsnails.
