In the lower site they got 26.7 kg/ha, which is below the 40 kg/ha mark that defines Class A streams. That's pretty typical for a freestone stream.

At the upper site they got 167.59. That's a very high number. It's rare that freestone streams have that high of a population. There is probably some "special" situation there that is leading to such a high number.

They might be getting some trout from the river that move up there when the river gets warm.

They should do another survey site further up the creek to get a better idea of the population.

I noticed that too and wondered if package plants are adding nutrients. Cause the streams in the park are pretty acidic in the headwaters. One of the culverts near the mouth is pretty impassable during low water.
