I am assuming that this topic has been spawned by the recent story that the PFBC will begin studies of previously fingerling stocked streams and their success (like the LJ-to some extent). And how the PFBC will determine new streams that may fit into a more expanded and "resource-first" driven program.

Do you have a reference to that story? Mike, one of the fisheries managers mentioned something about the issue of fingerlings vs. adult supplementation, but I got a different suspicion from it. I surmised that PFBC believes that stocking adult trout to supplement populations may be more cost effective than the fingerling stockings because of the very low survival rate of fingerlings and they were going to test the hypothesis with such studies.
